Abstract The effectiveness of twenty public search engines is evaluated using TREC-inspired methods and a set of 54 queries taken from real Web search logs. The World Wide Web is taken as the test collection and a combination of crawler and text retrieval system is evaluated. The engines are compared on a range of measures derivable from binary relevance judgments of the first seven live results returned. Statistical testing reveals a significant difference between engines and high intercorrelations between measures. Surprisingly, given the dynamic nature of the Web and the time elapsed, there is also a high correlation between results of this study and a previous study by Gordon and Pathak. For nearly all engines, there is a gradual decline in precision at increasing cutoff after some initial fluctuation. Performance of the engines as a group is found to be inferior to the group of participants in the TREC-8 Large Web task, although the best engines approach the median of those systems. Shortcomings of current Web search evaluation methodology are identified and recommendations are made for future improvements. In particular, the present study and its predecessors deal with queries which are assumed to derive from a need to find a selection of documents relevant to a topic. By contrast, real Web search reflects a range of other information need types which require different judging and different

YEARS OF CITING ARTICLES

Abstract:

In this paper, we present Google, a prototype of a large-scale search engine which makes heavy use of the structure present in hypertext. Google is designed to crawl and index the Web efficiently and produce much more satisfying search results than existing systems. The prototype with a full text and hyperlink database of at least 24 million pages is available at

↑ ABSTRACT

Research has reported that about 10&percent; of Web searchers utilize advanced query operators, with other 90&percent; using extremely simple queries. It is often assumed that the use of query operators, Boolean operators and phrase searching, improves the effectiveness of Web searching. We test this assumption by examining the effects of query operators on the performance of three major Web search engines. We selected one hundred queries from the transaction log of a Web search service. Each of the original queries contained query operators such as AND, OR, MUST APPEAR (+), or PHRASE (" "). We then removed the operators from these one hundred advanced queries. We submitted both the original and modified queries to three major Web search engines; a total of 600 queries were submitted and 5,748 documents evaluated. We compared the results from the original queries with the operators to the results from the modified queries without the operators. We examined the results for changes in coverage, relative precision, and ranking of relevant documents. The use of most query operators had no significant effect on coverage, relative precision, or ranking, although the effect varied depending on the search engine. We discuss implications for the effectiveness of searching techniques as currently taught, for future information retrieval system design, and for future research.

Abstract: There has been much recent interest in extracting information from collections of V that has been used is Ingwersen's Web impact factor. It has been demonstrated th this metric can produce results that correlate with research ratings of British univer despite being a measure of a purely Internet phenomenon, the results are suscepti interpretation. This paper addresses the question of which is the best possible dom from, if research is the focus of interest. WIFs for British universities calculated fro source domains are compared, primarily the .edu, .ac.uk and .uk domains, and the results show that all four areas produce WIFs that correlate strongly with research produce incontestably superior figures. It was also found that the WIF was less abl more homogeneous subsets of universities, although positive results are still possib

Abstract

With the web at close to a billion pages and growing at an exponential rate, we are faced with the issue of rating pages in terms of quality and trust. In this situation, what other pages say about a web page can be as important as what the page says about itself. The cumulative knowledge of these types of recommendations (or the lack thereof) can be objective enough to help a user or robot program to decide whether or not to pursue a web document. In addition, these annotations or metadata can be used by a web robot program to derive summary information about web documents that are written in a language that the robot does not understand. We use this idea to drive a web information gathering system that forms the core of a topic-specific search engine. In this paper, we describe how our system uses metadata about the hyperlinks to guide itself to crawl the web. It sifts through useful information related to a particular topic to eliminate the traversal of links that may not be of interest. Thus, the guided crawling system stays focused on the target topic. It builds a rich repository of link information that includes metadata. This repository ultimately serves a search engine.

Measuring end-user availability on the Web: practical exp

Merzbacher, M. Patterson, D.
California Univ., Berkeley, CA;

This paper appears in: [Dependable Systems and Networks, 2002. DSN 2002. Proceeding of the Conference on](#)

Publication Date: 2002

Current Version Published: 2002-12-10

Abstract

For service applications on a network, measuring availability, performance, and quality of traditional software and hardware measures are both inadequate and misleading. Better availability that incorporate end-user experience will lead to meaningful benchmarks and high availability services. We present the results of a series of long-term experiments that of select Web sites and services with the goal of duplicating the end-user experience. Using measurements, we propose a new metric for availability that goes beyond the traditional uptime.
